**INNOVATIVA KONSULTER**

*"The general approach adopting for accounting for potentially important uncertainties is the use of **conservative assumptions and data** in the modelling. This may lead to a **series of conservative assumptions** and as a consequence **some guideline values may be set with too much precautions.**"*

Areas where the further development of the methods used in this report would be most useful are:

- uptake of contaminants by plants
- transport of vapors into buildings
- bioavailability of contaminants
- etc

Toxicological data and ecotoxicological data naturally have a great impact on the risk evaluation. The tox-data are chosen from information available 1996. However, **tox-data are continuously being revised and updated** and therefore revised values may later appear in the literature.
