# $\|$ MULTICONSULT Ш Multidisciplinary Consulting Services **REMEDIATION DUE TO CREOSOTE CONTAMINATION** IN WETLANDS IN RÂDE, NORWAY Gunnar Brønstad

Multiconsult AS

#### **Content of this presentation**

- · Who is Multiconsult
- · Location of site
- · History of plant and investigations
- · Contamination and remediation at the plant site
- Contamination, risk assessment and remediation in the wetlands

Ш Ш

· Conclusion

Dato: Side: 2

# **MULTICONSULT**

Engineering.

MULTICONSULT is a leading multi-disciplinary company within consulting engineering. The main office is located in Oslo

Services

MULTICONSULT is working with all project stages, from the first idea to implementation and operation.

MULTICONSULT has competent professionals within our fields of activities and offers specialist services and complete planning and design within the following business areas: Buildings and Property, Industry, Oil and Gas, Infrastructure, Energy, Natural Resources and Environmental

MULTICONSULT's business are

Business areas Sarpsborg, Ski, Skien, Stavanger, Steinkjer, Tromsø, Trondheim,

Branch offices in Norway Bergen, Drammen, Egersund, Fredrikstad, Halden, Kristiansand, Moss Narvik Oslo Sandnes

Tønsberg and Ålesund. International business MULTICONSULT is working abroad through NORPLAN. We also have branch offices in Sweden, Uganda

and Tanzania.

# **MULTICONSULT**

MULTICONSULT offers specialist services and integrated planning within the business areas:

- Buildings and Property
- Industry
- Oil and Gas
  Transportation and Infrastructure
- Energy
- Environmental Engineering and Natural Resources

MULTICONSULT's business areas

### History of the plant

- Operated by NSB from ca. 1900 to 1943
- Mainly impregnating railway beams
- Creosote initially stored in three tanks under plant
- Unloading of creosote from railway carriage west of plant
- No knowledge of amount of beams impregnated or creosote used

III

#### **History of investigations**

- NGI 1992: 18 test pits, 15 drillings, 7 wells, 14 sedimentsamples (channel), 6 soundings, seismic surveying
- Jordforsk 1994-95: soil-, sediment- and porewatersampling, microtox, effect studies (plants, earthworms, mouse, snail), nitrification studies
- SCC 2001: channel water monitoring, 5 soil samples
- · Multiconsult 2004: 35 test pits at plant site
- Multiconsult 2003 2006: water monitoring program

First application of remediation permit sent SFT in 1997

Dato: Side: 13

#### Multiconsults involvment in the project (from 2003)

- Risk assessment and remediation plan
- Water monitoring (channel)
- Registering water level fluctuations
- Additional investigations of plant site
- Detailed remediation design and tender documents
- Meeting with contractor as needed during remediation

Ш

Ш

· Final report to SFT

Dato: Side: 14

#### **Extent of contamination**

- Plant site: ca. 4.200 m<sup>2</sup> is contaminated. Estimated cont. soil volume ca. 4.500 m<sup>3</sup>.
- Wetland: ca. 4.400 m<sup>2</sup> is contaminated. Cont. soil volume very roughly estimated to ca. 16.000 m<sup>3</sup>.
- Wetland: Free phase creosote registered in the 1990s in cracks in clay and along plant roots to several m depth. Strongly contaminated sediments in the old water channel through the wetlands.

Dato: Side: 18

#### **Risk assessment of plant site**

- Assumed future recreational area usage.
- The health related risk assessment concluded that the plant site is contaminated above calculated accept criteria for top soil.
- The remediation evaluation concluded that a clean top soil layer should be established on the plant site after removing strongly contaminated soil (PAH > 2.100 mg/kg)

### Remediation of the plant site

- Demolishing all existing buildings (ca 750 m2)
- Removing 113 m<sup>3</sup> contaminated water from the 3 creosote tanks underneath the plant. The tanks afterwards filled with clay
- Removing strongly contaminated soil with average PAHconcentration 3.500 mg/kg (323 tonn)
- Establishing a clean soil cover of 0,35 m clean soil and 0,15 m gardening mould on the whole site (6.300 m2) and sowing seeds of local grass
- Establishing a cut off trench for surface water upstream the site

Side: 20

August 2006

Ш

#### **Monitoring program**

- Regular water sampling since November 2003
- Monthly, weekly (during remedation) or bimonthly
- Analyses on PAH and partly oil and nutrients
- Generally steady and low concentrations

Side: 21

 With few exceptions well below Canadian Water Quality Guidelines

#### **Risk assessment wetlands**

- <u>Health:</u> the wetland contaminated above calculated accept criteria for top soil
- Environment:
  - Risk assessment based on a series of biological effect studies in the 1990s (microtox, plants, fish, earthworms, mouse, snails) and pore water sampling
  - The monitoring of the water in the channel has not documented any unacceptable migration of PAH / oil towards downstream areas
  - Sudden flush of contaminants may be possible during heavy rains
  - The effect studies are not conclusive
  - However no doubt that soil in some parts of the wetlands is poisonous, may locally affect certain plants and cause increased PAH-concentrations in earth worms etc (being food for birds and small mammals)
- Conclusion:
  - The ecosystem in the wetlands is probably not in general negatively affected
    The existing water channel passing the contaminated wetlands should be relocated (preventive remediation)
  - At the same time the water level in the Auberghølen lake should be stabilised

III

Ш

Dato: Side: 22

#### Assessing remediation alternatives

- Strong local and environmental interests in avoiding any permanent damage or alteration of the wetlands
- Cost benefit analyses of the following alternatives:
  - Relocation of channel, permanent high water level
  - Relocation of channel, permanent "normal" water level
     Removing contaminated soil
  - Removing contaminated soil
    A new, thick cover of clean soil
- Conclusion: Relocation of channel, permanent "normal" water level

### **Remediation of the wetlands**

- After SFT in April 2004 accepted the remediation plan with minor adjustments, detailed design and tender preparation was carried out.
- The remediation was then carried out from May – August 2005.
- There was a strong focus during the remediation of not damaging the wetlands permanently.
- An emergency plan and a monitoring plan was prepared.

Dato: Side: 25

## August 2006 – towards covered area

## **Remediation of the wetlands - summary**

- A new water channel (length 270 m)
- · Widening the down stream part of the existing channel
- A new culvert on the water channel under a local road with an adjustable wier (to stabilise the water level in the lake)
- A fish ladder so fish > ca. 7 cm may bypass the wier
- Existing channel that had been replaced (230 m) backfilled with clay.
- Covering the strongest contaminated part of the wetlands (1.700 m2) with 20 cm soil with high organic content, after cutting down but not removing existing vegetation of common reed.

Ш

Ш

Planting black alder (ca 260) and willow (ca 1850) along the new channel.

Dato: Side: 30

#### Conclusion

- · No unforeseen contamination occurred.
- The water level in the lake has been stabilised, fish is observed to easily move past the water ladder (and people fishing there)
- · The continued water monitoring show no contaminant migration.
- The ground underneath parts of the wetlands will however also in the future be strongly contaminated.

Ш

- In late August 2006 SFT and Jernbaneverket made a 1 year site inspection. SFT expressed their satisfaction with the project.
- It may take several years before it can be concluded that the wetlands has not been altered
